# Calling for an accurate forecast system in the Gulf of Mexico

Two pressing cases

Gulf  
Integrated  
Spill  
Research

# Calling for an accurate forecast system in the Gulf of Mexico

- ❑ Tropical Storms/Hurricanes forecast
- ❑ Oil spills tracking

Accurate forecast may help emergency response planning & management.

# Overview: Designing a real-time forecast system

Defining forecasting model, strategy, and parameters

# Designing a real-time forecast system

## Goals:

- ❑ Accuracy
- ❑ Automation
- ❑ Availability

# Designing a real-time forecast system

## Accuracy:

Use locally developed Coupled Regional Climate Model (CRCM)—couples WRF (3.4) and ROMS (3.5)

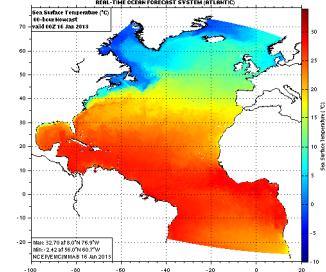

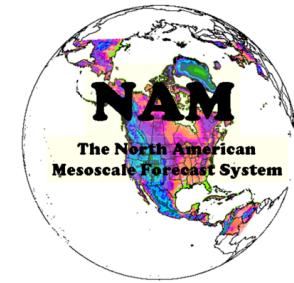

- ❑ CRCM should provide more accurate forecasts, since energy exchanges between the ocean and the atmosphere are being taken into account
- ❑ Energy exchange especially important when forecasting Tropical Storms/Hurricanes in the Gulf of Mexico
- ❑ Use of high-resolution grids (down to 1km) provides finer features in the output data.

# Designing a real-time forecast system

## Accuracy:

Initialize forecast model **every other day**—or **every day** in case of Tropical Storms/Hurricanes—using:

- ❑ Latest 84-hour atmospheric forecast data from NOAA NCEP's North American Mesoscale Forecast System (NAM)—available every 3 hours at 12km resolution—to initialize atmospheric model (WRF)
- ❑ Latest 3-day ocean forecast data from NOAA NCEP's Real-Time Ocean Forecast System (RTOFS) for the Atlantic Ocean—provided daily at ~5km resolution—to initialize ocean model (ROMS)

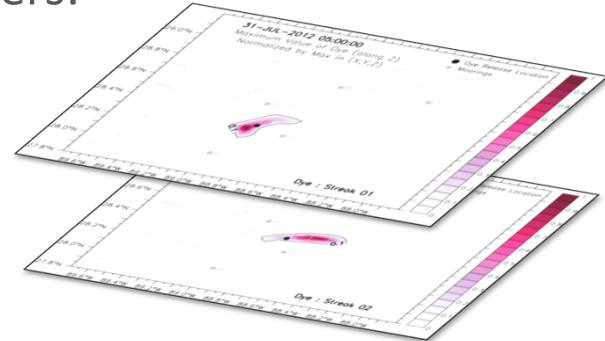

Hourly coupling atmosphere/ocean

# Designing a real-time forecast system

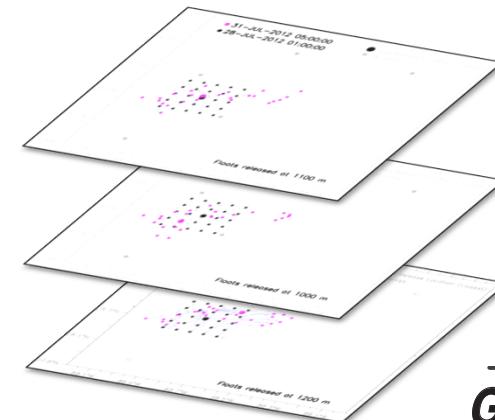

## Accuracy:

For tracking of oil spills, use **passive** tracers:

- Dyes “released” at the spill site

- Lagrangian floats, distributed across a few depth levels around the spill site

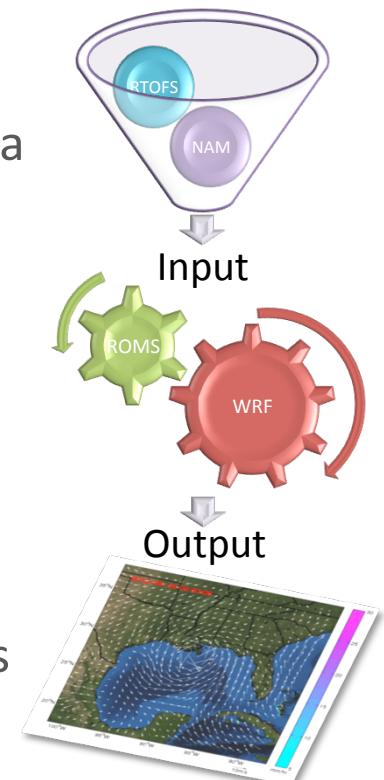

# Designing a real-time forecast system

## Automation:

Implement automatic scripts for:

- ❑ Preprocessing: download NOAA's data, remap data to CRCM grid, create initial and boundary conditions for CRCM
- ❑ Running CRCM
- ❑ Post-processing: Creating real-time forecast charts

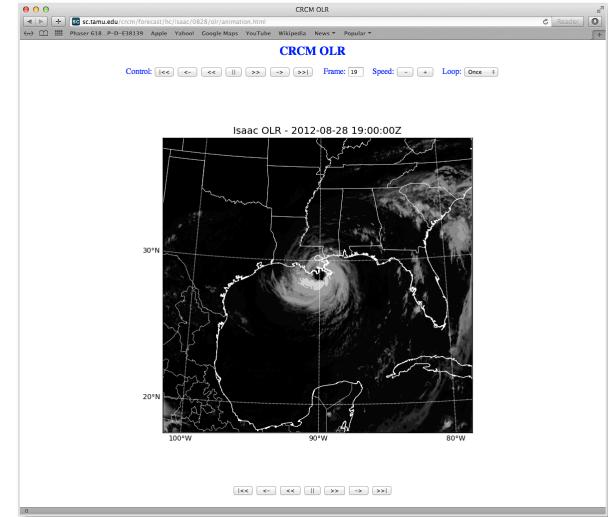

# Designing a real-time forecast system

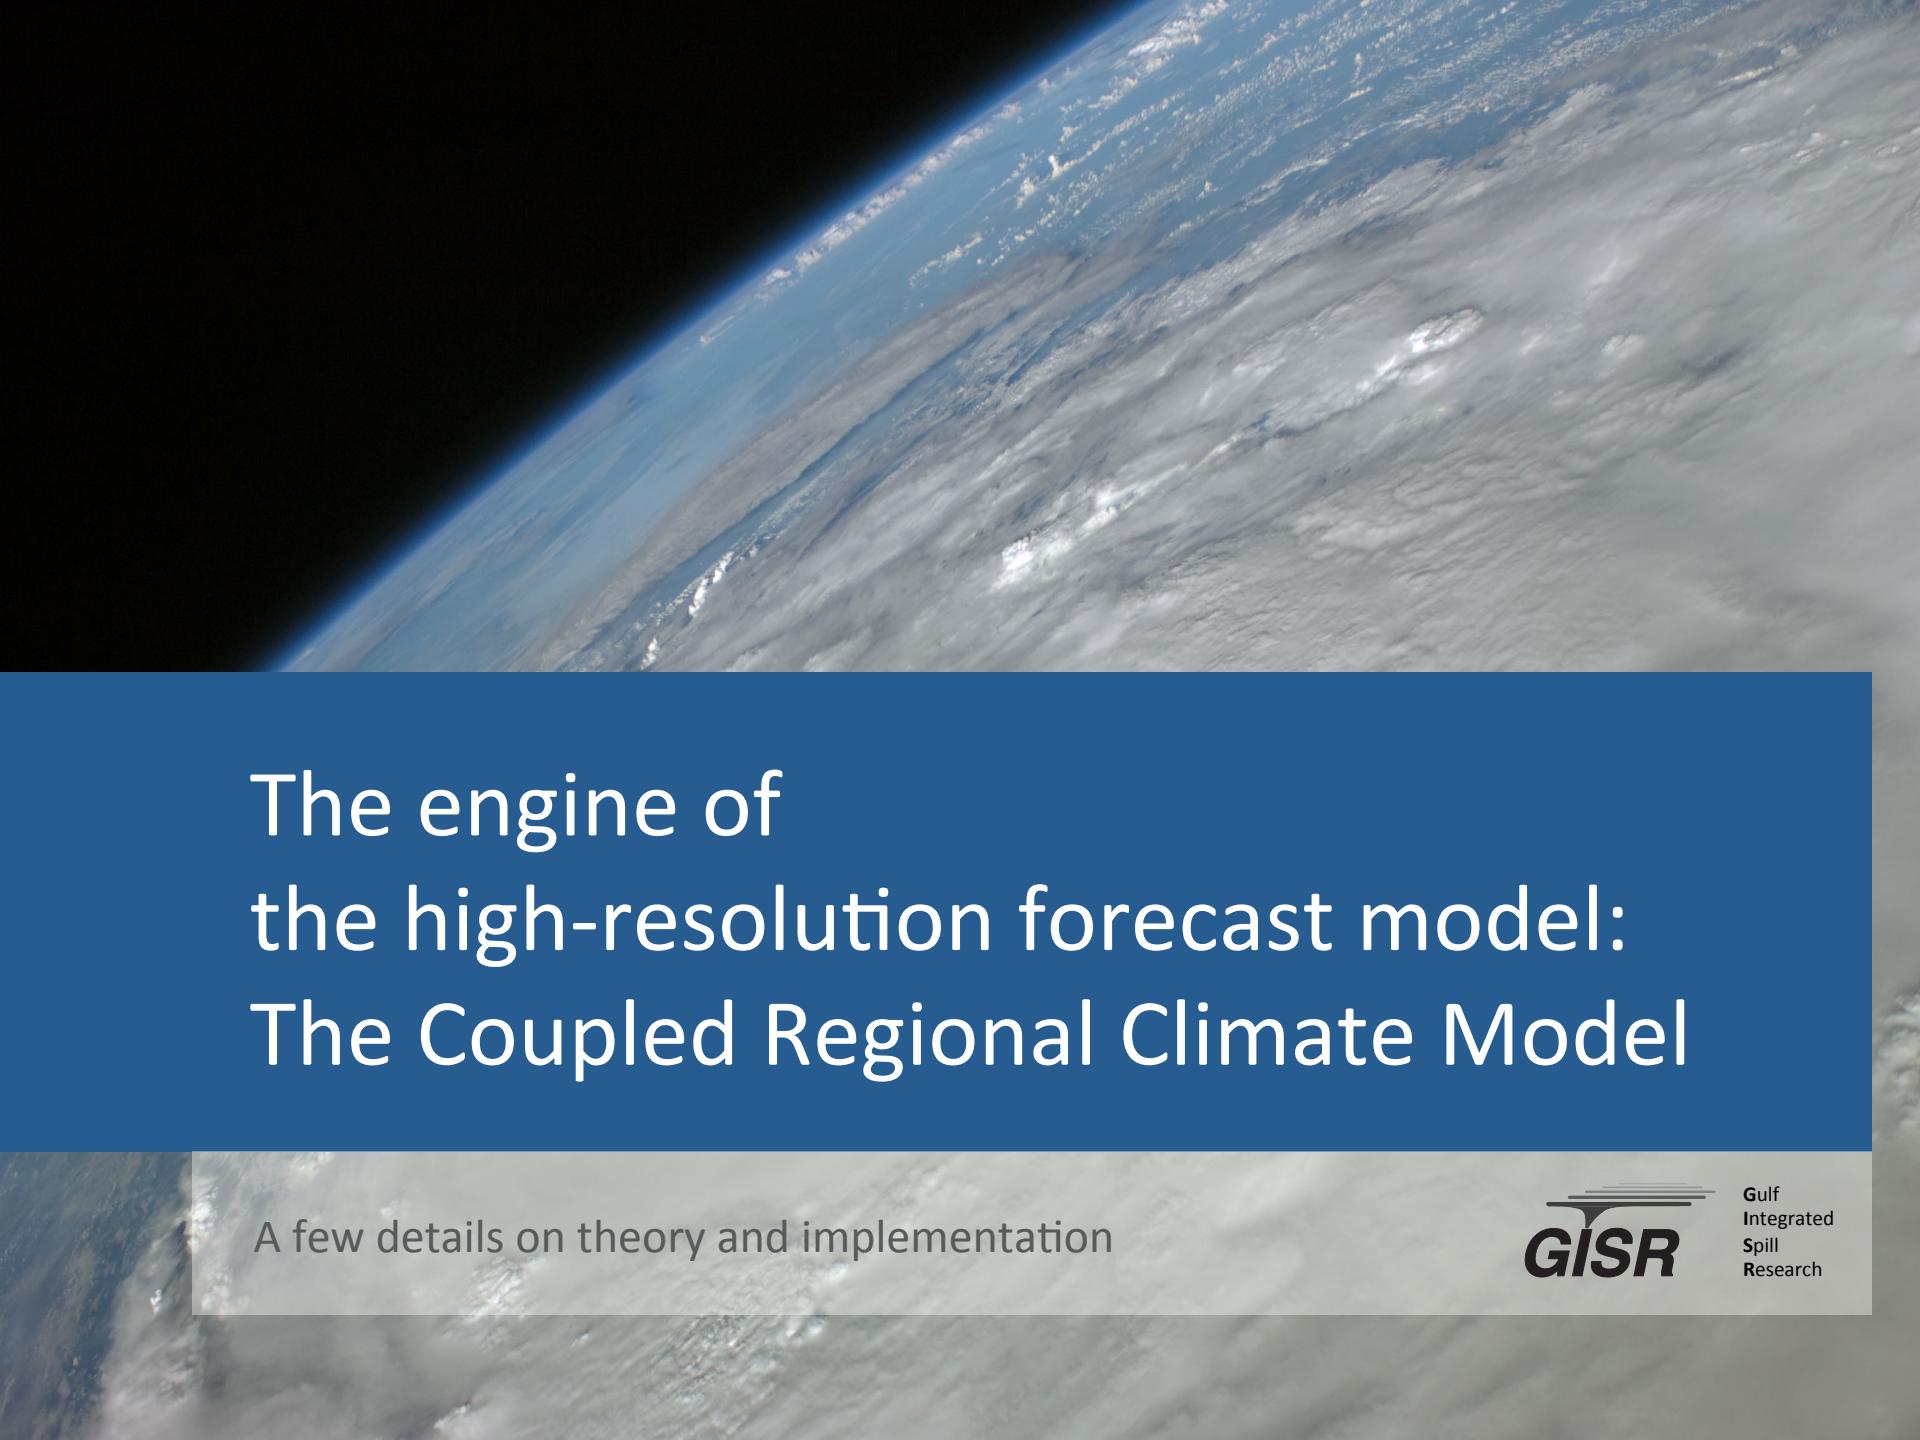

## Availability:

Make available atmosphere/ocean forecasts as they are produced

- ❑ Analyze, plot, and publish CRCM output data to the World Wide Web:
- ❑ Post hourly forecast charts **every 15 minutes**

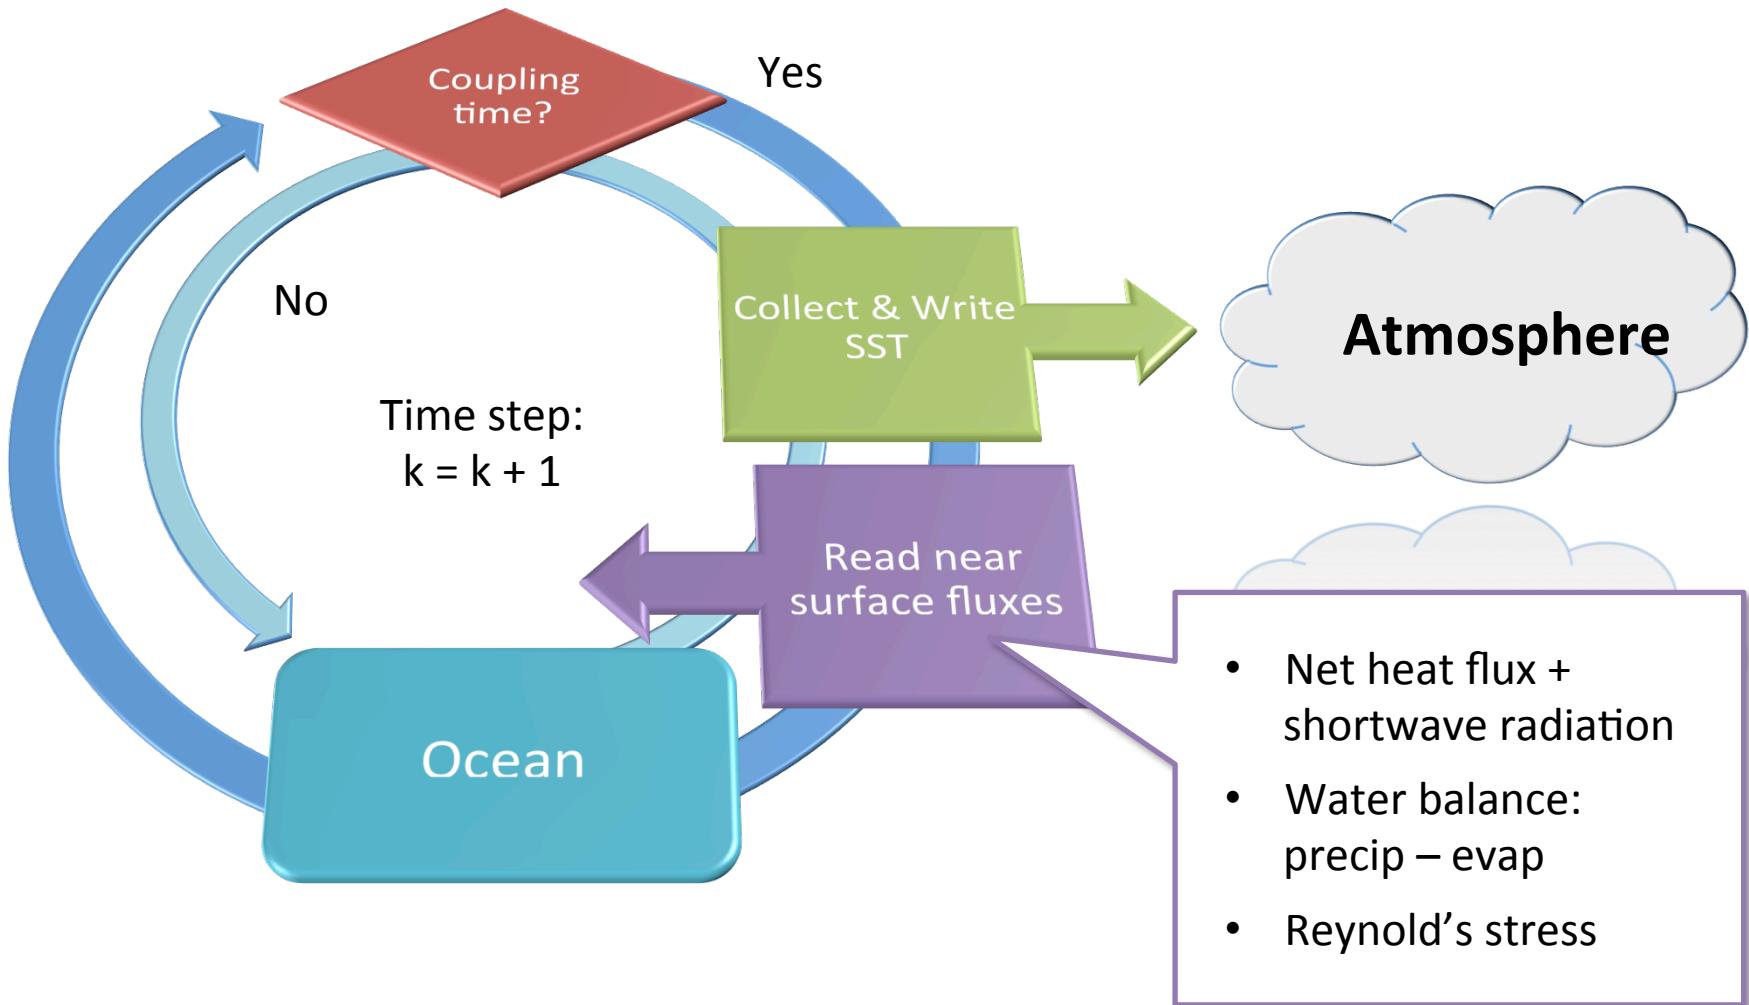

<http://sc.tamu.edu/crcm>

# The engine of the high-resolution forecast model: The Coupled Regional Climate Model

A few details on theory and implementation

# CRCM: The mechanics of coupling

# CRCM: The starting point ...

- ❑ **Regional Ocean Modeling System (ROMS) version 3.5**

ROMS/TOMS Framework: September 21, 2011

# The ignition key

## Main driver: **run\_forecast.sh**

- Creates WRF initial & boundary condition  
`create_crcm_input.sh`
- Creates ROMS initial & boundary conditions  
`create_roms.sh`
- Add initial and boundary conditions for tracers, if needed
- Creates CRCM run directory and input files for the forecast run
- Starts forecast by submitting a batch job to a reserved run slot on Eos

# Post-processing

Using:

- ❑ MATLAB to generate maps for wind, precipitation, SST, SSH, and storm intensity, and to upload them to the webserver  
`run_matlab.sh [YYYY-MM-DD]`
- ❑ Ferret to generate and upload tracer maps  
`run_ferret.sh [YYYY-MM-DD]`
- ❑ NCL for preprocessing
- ❑ NCO for postprocessing tasks
- ❑ Using GrADS/Python for further analysis

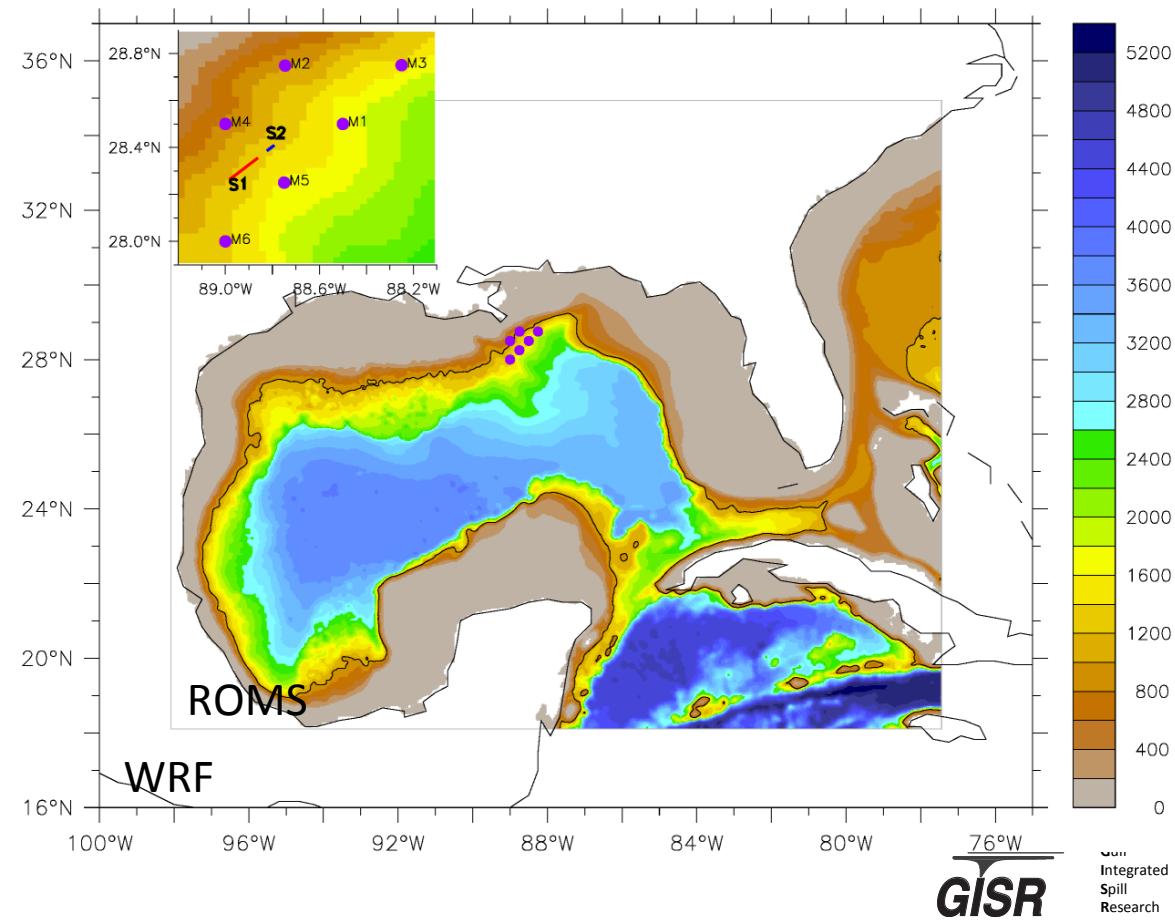

# Forecast setup

Model parameters and strategy for real-time forecast

# CRCM model setup

- Define identical 3km rectangular lat/ion grids for both the atmosphere and ocean domains over the Gulf of Mexico
- 2 dyes at the experimental release sites: S1, S2
- 243 Lagrangian floats, uniformly distributed in square (9x9) patches at three depths: 1,000m; 1,100m; 1,200m

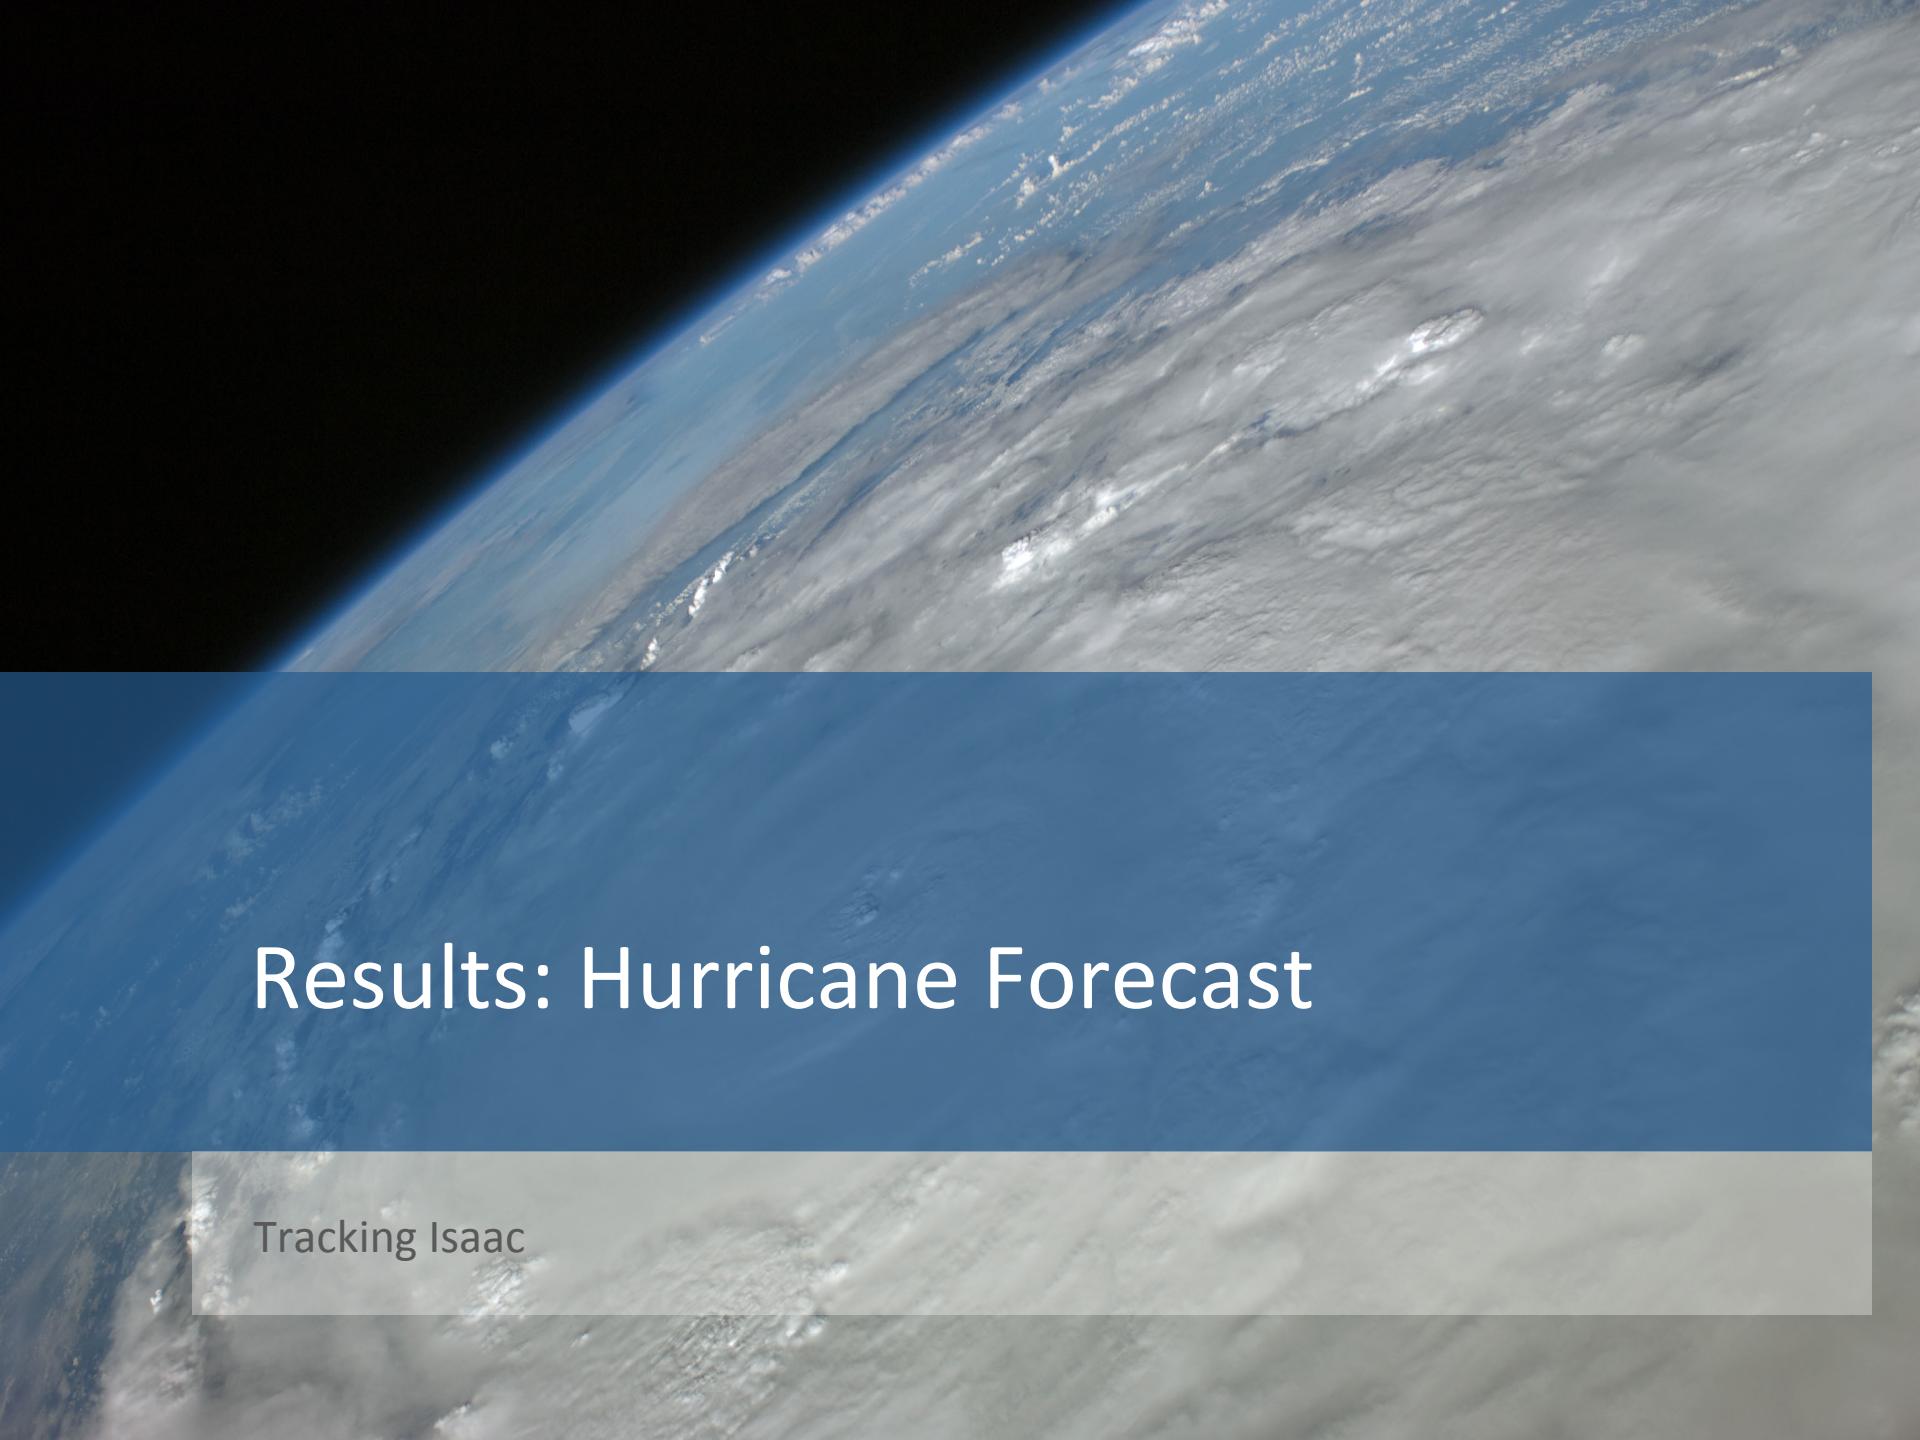

# CRCM model details

- Atmosphere horizontal grid @ 3km resolution:
  - 856 (lon) x 811 (lat) = 694,216 points
  - 35 vertical levels
- Ocean horizontal grid @ 3km resolution:
  - 720 (lon) x 660 (lat) = 475,200 points
  - 50 vertical levels (stretched coordinate)
- Run forward for 84 hours simulated time on 704 cores (88 nodes) on Eos: 624 WRF + 80 ROMS
- Total downloaded data ~ 1.5 GB (NAM: 716.5 MB, OFS: 796.6 MB)
- Amount of data generated in one run (with tracers): 482 GB
- Wall clock time/run: ~7.5 hours / 14 hours (with tracers)

# Generated forecast

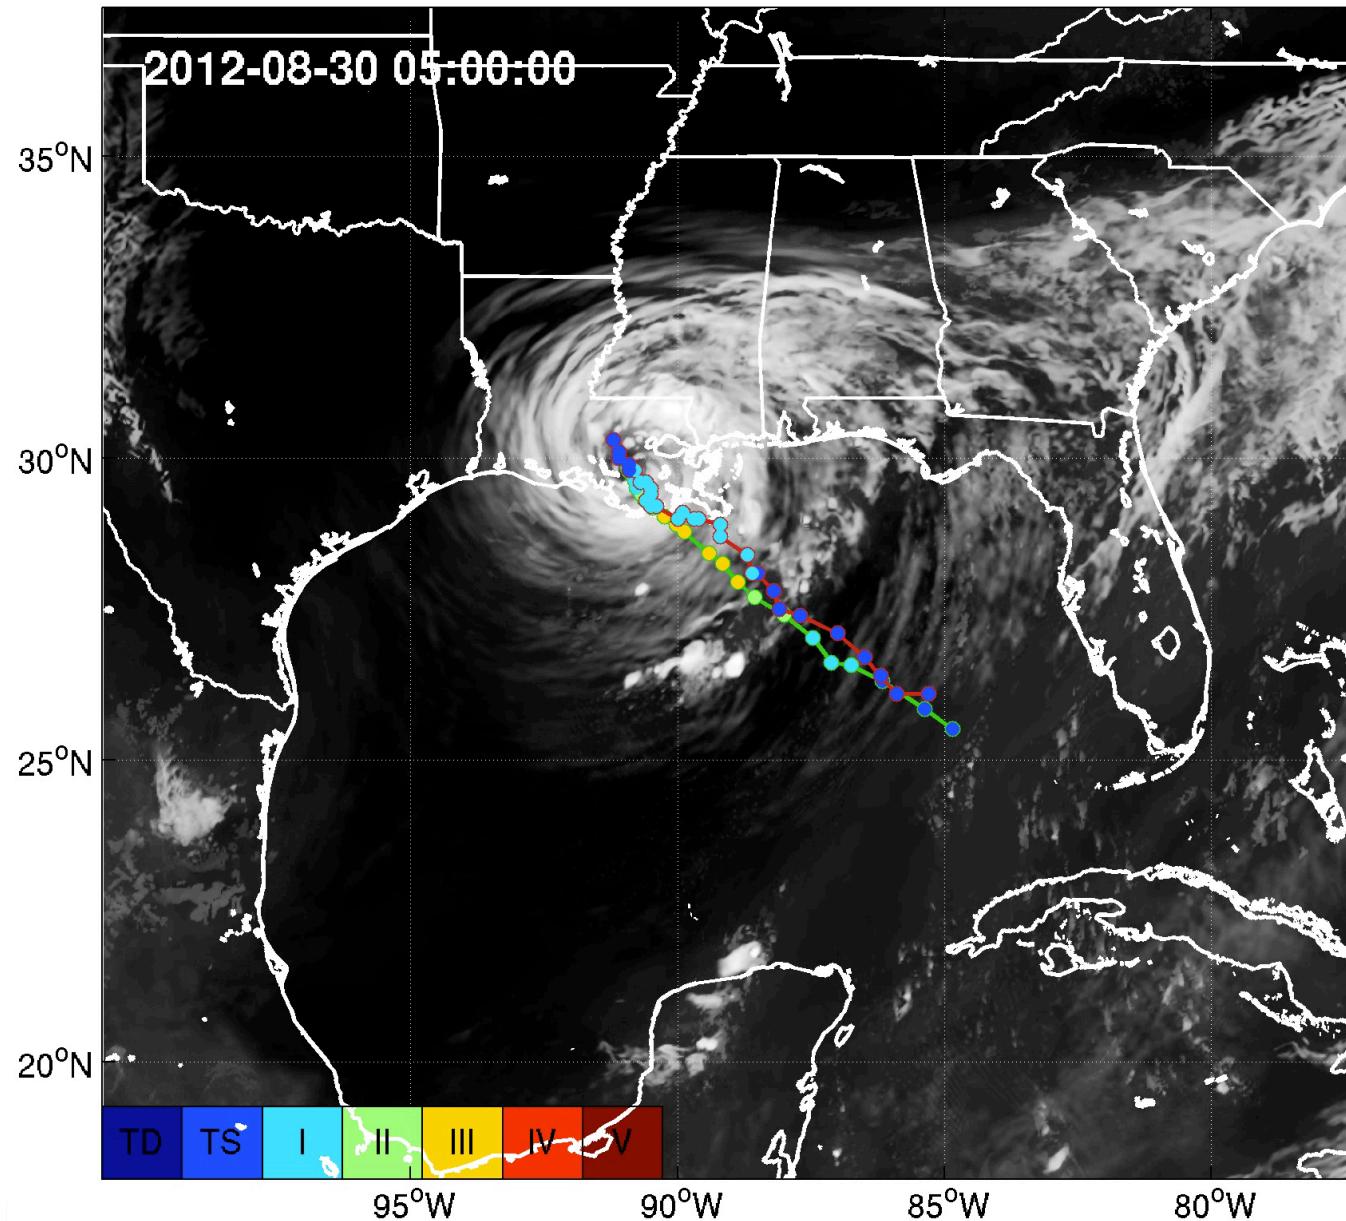

- Produce **hourly** forecast maps for:
  - Wind (10m) and precipitation rate
  - Sea Surface Temperature
  - Subsurface velocity at 1,100 m
  - Distribution of dye #1 & #2
  - Trajectories of Lagrangian floats at 1,000m, 1,100m, and 1,200m
  
- Additionally:
  - Sea Surface Height
  - Storm Intensity
  
- Full dataset available through a THREDDS server:  
<http://pong.tamu.edu/thredds/catalog.html>

The background of the slide is a photograph taken from space, showing the curvature of the Earth. The planet's surface is covered in various cloud formations and some landmasses are visible. The horizon line is tilted to the left.

Tracking Oil Spills in the Gulf of Mexico

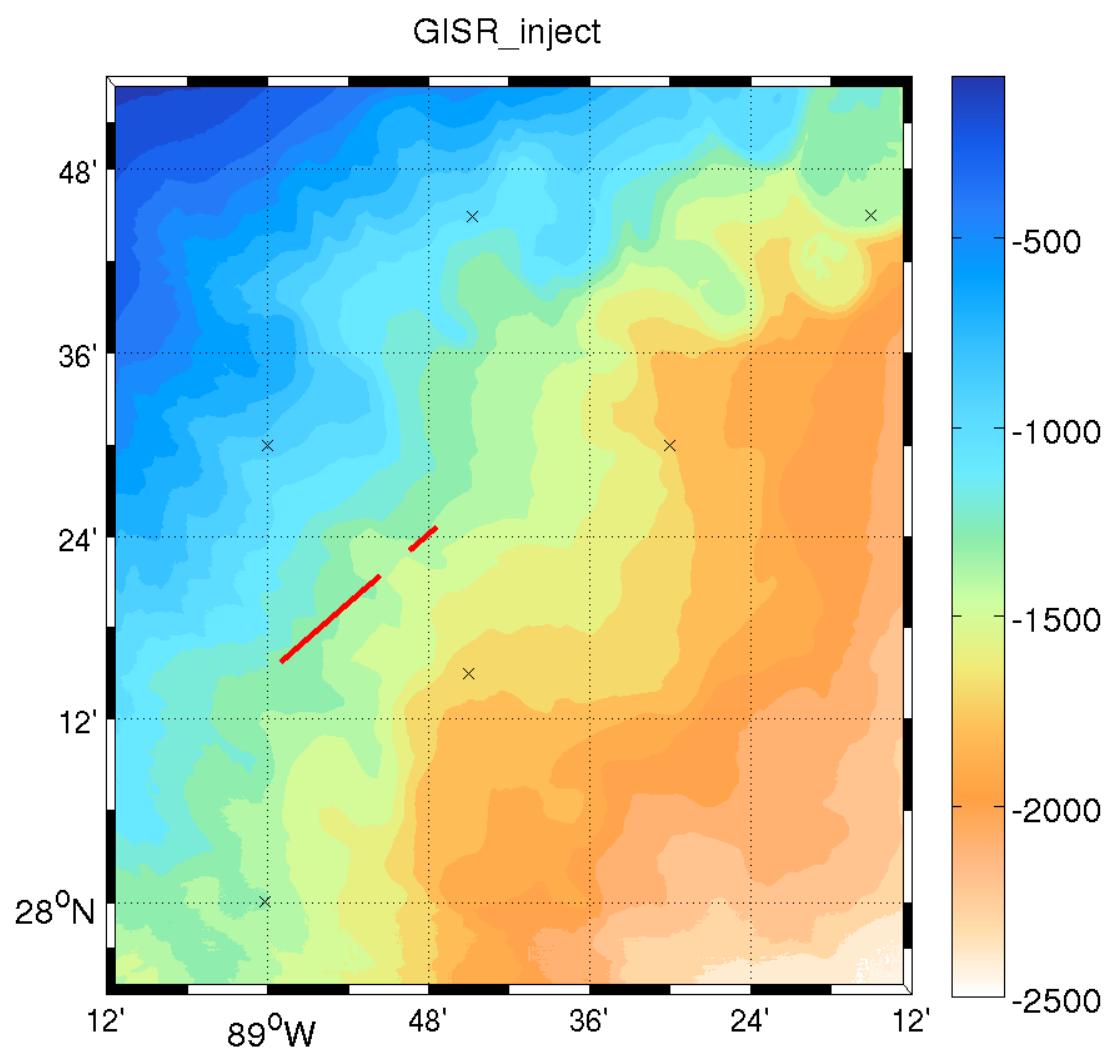

# Deep Release Experiment: July 26-Aug 9

- James R. Ledwell - Woods Hole Oceanographic Institution Woods Hole, MA

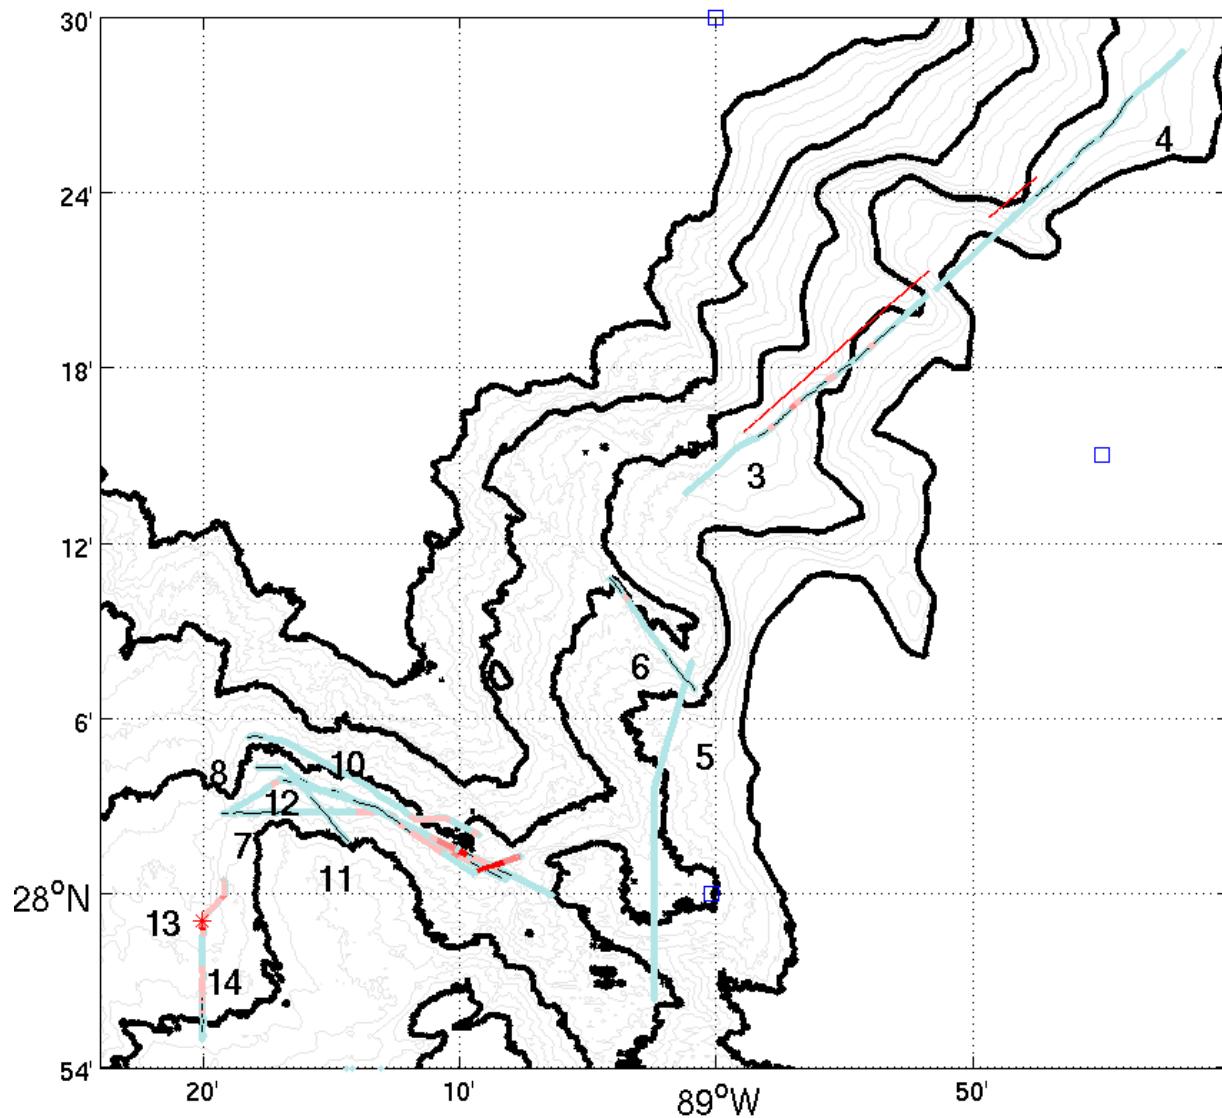

# Deep Release Experiment: July 26-Aug 9

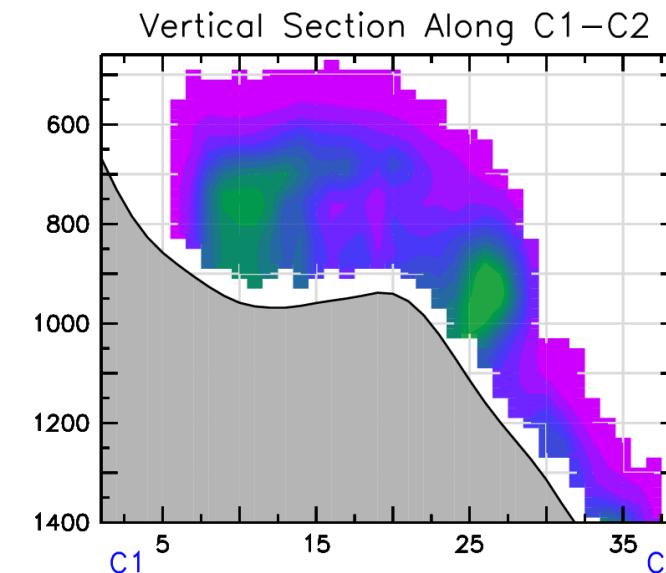

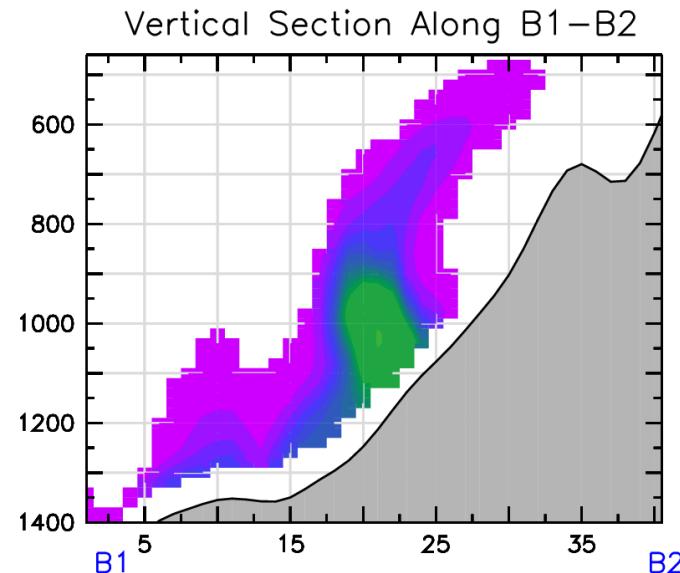

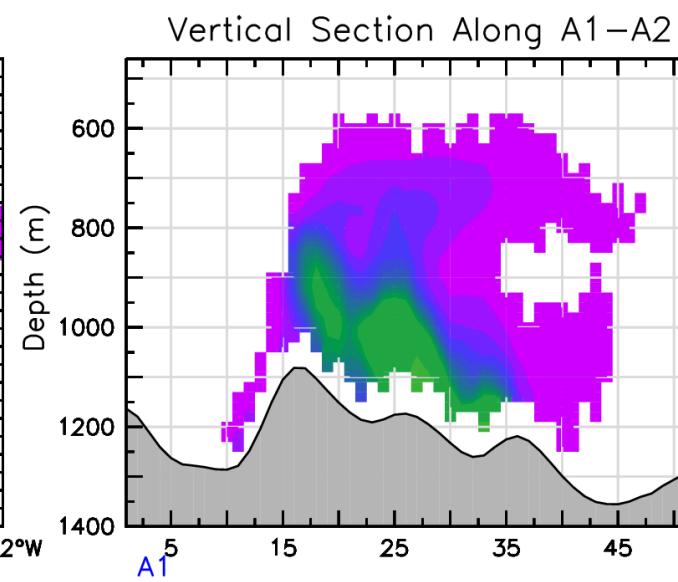

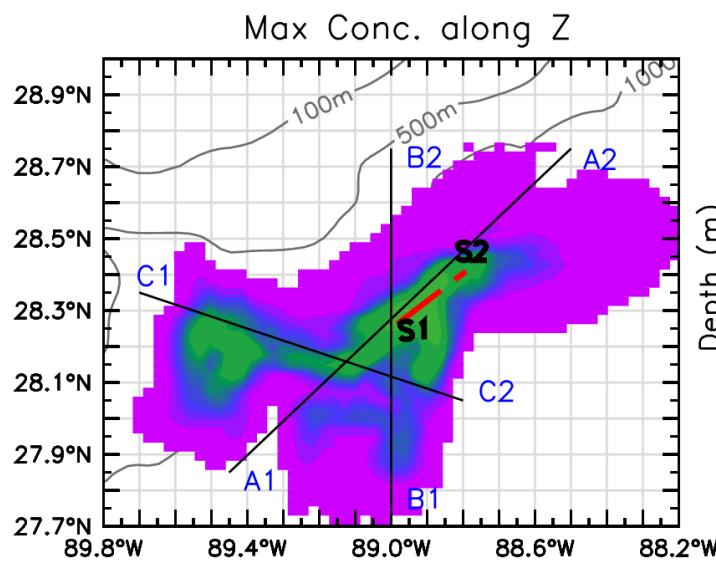

- Released 16.8kg  $\text{CF}_3\text{SF}_3$  in two streaks at 1,090 to 1,180 dbar on July 28, 2012
- Released RAFO floats
- Moorings (x) set in previous cruise (Steve Di Marco) guided tracer release
- Accurate numerical simulations requested to predict tracer dispersion
- Simulation model will help responses to accidental oil spills in the Gulf

# Summary

- A Real-Time, High-Resolution forecast system is available for the ocean and atmosphere over the Gulf of Mexico
- Based on a 3km-resolution Coupled Regional Climate Model (WRF/ROMS)
- Used to predict Tropical Storms/Hurricanes and to track oil spills via passive tracers
- Results available to the community through the Web
- Validation still underway, but early results look promising
